**Abstract**

Existing classifications of developing countries have been based on – or in some cases dominated by – income per capita (such as the World Bank's low, middle and high income thresholds), thus neglecting the multidimensionality of the concept of 'development'. Even those deemed to be 'alternatives' to the income per capita classification, such as the Human Development Index and Least Developed Country classifications, include income per capita as a component which is - arguably - heavily weighted. The result of this is that, operationally, aid agencies may well be forgiven for being confused as to where to spend Official Development Assistance (ODA). This paper proposes an alternative approach to classifying countries. We

build five clusters of developing country through and develop the taxonomy further by considering changes over time since the late 1990s to the groups themselves, to the countries in each group and to the developing world as a whole.

**Key words:** Development taxonomy, Country classification, Human development, Poverty, income levels.

## **Paper**

**Thematic Area:** Human development

## 1. Introduction

Classifying developing countries serves two important purposes: First, for *analytical reasons*, country classifications simplify a complex and diverse world into relatively homogeneous groups of countries that share some distinct features, thus supporting understanding of the most significant inter-country differences (or similarities) in development outcomes. Second, for *operational reasons*, country classifications serve a purpose for multilateral and bilateral aid agencies in terms of resource allocations and differentiated policies towards different countries. In short, a better understanding of the nature of differences between countries means resources and policies can be better tailored to suit countries' needs and potentially support the identification of countries with similar development needs.

However, existing classifications of developing countries are arguably excessively 'economistic' by been based on – or dominated by – income *per capita* (such as the World Bank's low, middle and high income thresholds), thus neglecting the multidimensionality of the concept of 'development'. Even those deemed to be 'alternatives' to the income-based classification, such as the Human Development Index (HDI) and Least Developed Countries (LDC) classifications, have income *per capita* – arguably – heavily weighted. The result of this is that, operationally, aid agencies may well be forgiven for being confused as to where to spend ODA given that some countries that are much better off in *per capita* income terms may well have surprisingly large proportions of their population living under \$2 – or even \$1.25 – poverty lines (Sumner, 2012). Certainly even undeniably better off countries such as China or Indonesia still have many of their population below the \$2 poverty line let alone the US poverty line of \$13/day (see Ravallion, 2010).

Not surprisingly, in one recent review of country classifications used by aid agencies, Nielsen (2012) argues that the methodology behind such taxonomies lacks clarity:

Existing taxonomies suffer from lack of clarity with regard to how they distinguish among country groupings. The World Bank has not explained why the threshold between developed and developing countries was a *per capita* income level of US\$6,000 in 1987 and US\$12,475 in 2011. Nielsen (2012: 17).

Additionally the subject of classification enquiry is a moving target: In the late 1990s most developing countries were classified by the World Bank as low income countries. Today most are middle income countries. Given that the World Bank country thresholds are only adjusted for “international inflation” in an attempt to keep their ‘real’ value constant (see discussion in Sumner, 2012), this means that in real terms the threshold has been fixed for 40 years so, and as countries have grown, more and more have passed this ‘fixed’ line.

In the precursor to this current paper we proposed an alternative approach to classifying countries (see Tezanos and Sumner, 2013) which is based on four frames on the meaning of ‘development’ that have been dominant in the academic literature for some considerable time: structural change, human development, environment sustainability and improved governance. Of course there are other potential ‘frames’ that we did not include as we considered that they are still evolving conceptually and empirically and remain highly contested in measurement.<sup>1</sup>

The choice of four frames we took is somewhat similar to that of two recent papers (Pritchett *et al.*, 2010; Pritchett and Kenny, 2013). Pritchett *et al.* (2010: 3-4) note thus:

When people speak of the ‘development’ of societies most people refer, implicitly or explicitly, to a cumulative historical process whereby economies grow through enhanced productivity, prevailing political systems represent the aggregate preferences of citizens, rights and opportunities are extended to all social groups, and organizations function according to meritocratic standards and professional norms (thereby becoming capable of administering larger numbers of more complex tasks). A given society undergoes a four-fold transformation in its functional capacity to manage its economy, polity, society and public administration, becoming, in time, developed... When in everyday speech people say that France is ‘more developed’ than Congo, or Denmark more developed than Nepal, they mean, inter alia, that France has undergone more of this four-fold functional transformation than the Congo and Denmark than Nepal.

Our review in Tezanos and Sumner (2013) of the academic literature of various development conceptions took us to a similar approach in the sense of economic,

---

<sup>1</sup> For this reason we did not claim our taxonomy was the final word, rather an illustration of the enduring weakness of income per capita to capture the many dimensions of development.

social and political development but with two important differences: First we added environmental sustainability and second we find if anything there is no such linear pattern in the data – as if all countries were following a similar ‘development path’ of income growth.

In this follow up paper we consider again our four frames which produced five clusters of developing country and develop the taxonomy further by analysing changes over time to the groups themselves and the countries in each group in order to answer the essential question: How has the developing world changed since the late 1990s?

The value-added of this paper is not to suggest our classification is the end in itself, nor to propose that it should be used by aid agencies. Rather, the intended contribution of the paper is to demonstrate the weakness of existing classifications given an evolving developing world and we thus propose the area of taxonomies is worthy of further exploration.

The paper is structured as follows. Section 2 discusses three country analytical classifications in common usage. Section 3 presents the theoretical basis and the methodology for building a multidimensional and dynamic taxonomy of countries using cluster analysis. Section 4 discusses the main results and compares the outcome of the cluster classification with other international classifications of development. Section 5 concludes.

## **2. Main classifications of developing countries**

It is not easy to classify countries according to their levels of development, to begin with because any definition of “development” is complex and multidimensional. Added to this difficulty is the fact that the socio-economic realities of the so-called “developing countries” are becoming more diverse and heterogeneous, which makes universally valid analysis even more difficult (Tezanos and Quiñones, 2012).

Despite these difficulties, there are several international classifications of development that use different criteria to draw some kind of threshold that separates the “developed” and the “developing” countries. Five well known classifications are: the low/middle/high income countries as used by the World Bank; the OECD’s Development Assistance Committee (DAC)’ classifications of ‘developing countries’ and “fragile and conflict-affected states”; the HDI of the United Nations Development

Programme (UNDP); and the Least Developing Countries (LDC) of other multilateral agencies such as the United Nations Conference on Trade and Development (UNCTAD), amongst others.

The World Bank provides, since 1978, a ranking of countries according to their corresponding levels of *per capita* income (proxied by the *per capita* Gross National Income, GNI, based on the Atlas method, largely an exchange rate conversion). Although the World Bank recognizes that development is not only a matter of income, it believes that the *per capita* GNI is ‘the best single indicator of economic capacity and progress’ (World Bank, 2014a). Thus, the successive *World Development Reports* (and the online database, the *World Development Indicators*) classify countries into four income groups using thresholds at about \$1,000, \$4,000 and \$12,000 *per capita* which are adjusted each year by international inflation (World Bank, 2014b). The resulting four country groups are called “low income countries” (LIC), “lower middle income countries” (LMIC), “upper middle income countries” (UMIC) and “high income countries” (HIC).

The OECD-DAC uses the World Bank’s income classification in order to distinguish two groups of countries (DAC, 2014): the “developing countries” (LIC, LMIC and UMIC, according to the World Bank), and the “developed countries” (basically high-income countries). The former are potential recipients of Official Development Assistance (ODA). Moreover, the DAC classification divides the LIC group into ‘Least Developed Countries’ (LDC, see below) and ‘other low income countries’.

One could argue that LIC and middle income countries (MIC) thresholds are worthy of a substantial review, particularly because they are so dated.<sup>2</sup> The exact methodology to set the lines is not public but the World Bank website states it was based on the relationship between income *per capita* and various other indicators of economic and social development presumably on whatever data was available in the late 1960s. Since then the lines have been revised by “international inflation”, meaning the inflation rates of the world’s richest countries (the weighted average of the Euro Zone, Japan, the U.K. and the U.S.). In short, there is now some 40-50 years of new data available since the thresholds were originally established to

---

<sup>2</sup> The World Bank itself has recently opened a review of the thresholds probably reporting by mid to late 2014. In a similar vein, the United Nations’ Development Cooperation Forum of the Economic and Social Council (ECOSOC) is reviewing the subject of country classifications.

assess if GNI *per capita* is closely related to other indicators of economic and social development. Further, “international inflation” ought now to include China and other ‘emerging economies’ in its calculation. And, indeed, it should be considered whether the use of ‘international inflation’ rates for the world’s richest countries is an appropriate way to assess the income thresholds over time for the world’s poorer countries, which may historically have had inflation rates above the ‘international inflation’ rate. There are also questions as to whether purchasing power parity (PPP) income should be used rather than exchange rate and if the thresholds should be fixed in real terms or linked to the world’s GNI *per capita*. In fact, the LIC/MIC threshold has been falling as a proportion of the world GNI *per capita* as Nielsen (2012) noted.

The OECD-DAC also has a grouping of “fragile and conflict affected countries”. Initially, three separate sources presented different classification criteria of “fragile states” (Brookings, Carlton and the World Bank).<sup>3</sup> The last of these, the World Bank’s ‘Harmonised Lists of Fragile Situations’ of 34 countries (see World Bank, 2013) arguably has a stronger analytical basis because:

‘Fragile Situations’ have: either a) a harmonized average CPIA [Country Policy and Institutional Assessment] country rating of 3.2 or less, or b) the presence of a UN and/or regional peace-keeping or peace-building mission during the past three years. This list includes only IDA eligible countries and non-member or inactive territories/countries without CPIA data. It excludes IBRD only countries for which the CPIA scores are not currently disclosed (World Bank, 2013: 1).

The OECD (2010) first combined the three lists into a list of 43 countries. As noted in Sumner (2010), only 17 of those 43 ‘fragile states’ were common across the lists, and the differences in the countries listed mean the proportion of the world’s poor in fragile states in 2007 ranged from 6 per cent to 25 per cent (see detailed critique of the ‘fragile states’ lists from Harttgen and Klasen, 2010). Then OECD (2013) revisited the OECD-DAC category and only the World Bank list of conflict/post-conflict countries was merged with a further source, the Failed States Index of the US think-tank, the Fund for Peace, which had the effect of producing 45 countries:

---

<sup>3</sup> See respectively for Brookings and Carlton: [www.brookings.edu/reports/2008/02\\_weak\\_states\\_index.aspx](http://www.brookings.edu/reports/2008/02_weak_states_index.aspx) and [www.carleton.ca/cifp](http://www.carleton.ca/cifp)

The list of countries in fragile situations used for this analysis (neither an official DAC list nor an official definition) [...] is a compilation of two lists: the Harmonised List of Fragile Situations (2009; World Bank, African Development Bank, Asian Development Bank) and the 2009 Fund for Peace Failed States Index. (OECD, 2013: 1).

Further, if more than a third of all developing countries fall under the OECD's definition of fragile and conflict states this sets up a binary that countries are either "fragile" or "stable". In reality stable countries may have fragile or conflict-affected sub-national units (e.g. India's Naxalite insurgency) and fragile and conflict states may have largely stable areas.

The UNDP ranks countries by levels of "human development" by means of a composite index – the *Human Development Index*, HDI – that tries to capture the multidimensionality of the development process. The HDI was first developed by Mahbubul Haq with the collaboration of Amartya Sen and other leading development thinkers for the first *Human Development Report* (see UNDP, 1990). Specifically, the index includes three dimensions of development: health, education and living standards. The HDI classifies countries into four relative groups of human development: very high, high, medium and low human development (UNDP, 2013):

The primary critiques of the UNDP classification have been that the HDI is only a partial and somewhat uneven application of human development and capabilities. It does not incorporate a full range of the conditions of human development (such as being sheltered) but only certain capabilities, and, although exchange entitlements are accounted for, endowments are not, and because 'capabilities' are difficult to measure, many of the components of the HDI are actually based on 'functionings' or outcomes rather than opportunities to achieve desirable outcomes. Further, it has been argued that the HDI shows little more than income *per capita* (due to the heavy weighting of GDP per person, which accounts for one third of the index) and the index components themselves correlate very closely (for further discussion, see Desai, 1991; McGillivray, 1991; Srinivasan, 1994).

Finally, there is also the UN category of 'Least Developed Countries' (LDC), which utilises a sophisticated methodology that combines human assets (including nutrition, child mortality, school enrolment and adult literacy), economic vulnerability (measures of the instability of agricultural production, population displaced by natural

disasters, instability in exports, and the share of agriculture in GDP and exports), proxies for economic ‘smallness’, ‘remoteness’ and GNI *per capita*. The main problem of the LDC category is that it is somewhat static. Guillaumont (2009), among others, has argued how the graduation criteria make it very difficult for countries to “leave” this category (even if they wish to). Furthermore, a third of LDC are actually MIC which somewhat undermines the sense of the LDC being the poorest countries across a set of dimensions if a third are, at least in income *per capita* terms, not amongst the poorest. And finally, the LDC category is not actually a development classification, as it groups countries in a binary way in which there is not criterion for identifying the “non-LDC” (they are just those not deemed as LDC).

### **3. A multidimensional and dynamic taxonomy of developing countries**

#### **3.1. Revisiting the dimensions of development**

In Tezanos and Sumner (2013) we review the history of thinking about ‘development’ over the last 50 years, and identify four conceptual frames in the literature on the meaning and measurement of development. These are: i) ‘development as structural transformation’; ii) ‘development as human development’; iii) ‘development as democratic participation and improved governance’; and iv) ‘development as environmental sustainability’. Other recently emerging ‘candidates’ might include ‘subjective wellbeing’ and ‘state capabilities’ (or ‘fragilities’). We did not include these last two frames in our development taxonomy as we felt that both are still evolving conceptually and empirically and remain highly contested in meaning and measurement. That is not to say the indicators we chose are without contention; merely that they are less contentious and better conceptually established to some considerable extent, and have better developed international data sets. Moreover, some aspects of state fragility are captured by the governance and democracy measures.

Following this review on different development conceptions we identified indicators for each frame. **Table 1** outlines the indicators chosen.<sup>4</sup> It is worth noting that any choice of indicators is arbitrary to a certain extent: the question is how

---

<sup>4</sup> See Appendix 1 for descriptive statistics of the data set.

arbitrary are they and to what extent the data is well used by other researchers. It is also important to note that for the exercise of constructing an international taxonomy we require indicators for which there are well-established data sets with good cross-country coverage. So the choice of indicators, to a considerable extent, is determined by what data is available that fits the four development conceptions for the majority of the developing countries.

**Table 1. Development dimensions and data used**

Development dimensions	Sub-dimensions	Proxies	Sources	Methods of construction
<b>I. Development as structural transformation</b>	2.1. Structural change	GDP in non-agricultural sectors (% of GDP)	World Bank (2012)	5-years averages
	2.2. Dependency on natural resources	Exports of primary commodities (% of GDP)	UNCTAD (2012) and World Bank (2012)	5-years averages
	2.3. Labour productivity	GDP per worker, PPP (constant 2005 \$)	Heston <i>et al.</i> (2011)	5-years averages
	2.4. Innovation capacities	Scientific articles (per million inhabitants)	World Bank (2012)	5-years averages
	2.5. External finance	(ODA+FDI+portfolioinvestment+remittances)/GDP	DAC (2012) and World Bank (2012)	5-years averages
<b>II. Development as human development</b>	1.1. Poverty	Poverty headcount (2\$ PPP a day)	World Bank (2012)	Closest available years
	1.2. Inequality	Gini coefficient	Solt (2009)	Closest available years
	1.3. Health	Malnutrition prevalence, weight for age (% of children under 5)	World Bank (2012)	5-years averages
<b>III. Development as democratic participation and improved governance</b>	3.1. Good governance	World Governance Indicators (WGI)	Kaufmann <i>et al.</i> (2011)	2-years averages of 6 governance indicators
	3.2. Quality of democracy	POLITY 2	Marshall and Jaggers (2011)	5-years averages
<b>IV. Development as environmental sustainability</b>	4.1. Environmental sustainability	CO <sub>2</sub> emissions (metric tons <i>per capita</i> )	World Bank (2012)	5-years averages

GDP: Gross Domestic Product. PPP: Purchasing Power Parity. FDI: Foreign Direct Investment. ODA: Official Development Assistance.

### 3.2. Methodology: a cluster analysis of developing countries

Cluster analysis is a numerical technique that is suitable for classifying a sample of heterogeneous countries in a limited number of groups, each of which is internally

homogeneous in terms of the similarities between the countries that comprise it.<sup>5</sup> Ultimately, the goal of cluster analysis is to provide classifications that are reasonably ‘objective’ and ‘stable’ (Everitt *et al.*, 2011): ‘objective’ in the sense that the analysis of the same set of countries by the same numerical methods produces similar classification; and ‘stable’ in that the classification remains similar when new countries – or new characteristics describing them – are added. Nevertheless, – as we will discuss below – the ‘stability’ may not hold over time when countries are changing.

Specifically, hierarchical cluster analysis allows one to build a taxonomy of countries with heterogeneous levels of development in order to divide them into a number of groups so that: i) each country belongs to one – and only one – group; ii) all countries are classified; iii) countries of the same group are, to some extent, internally ‘homogeneous’; and iv) countries of different groups are noticeably dissimilar. The advantage of this procedure is that it allows one to discern the ‘association structure’ between countries, which – in our analysis – facilitates the identification of the key development characteristics of each cluster.

Furthermore, cluster analysis deals with two intrinsic problems in the design of a development taxonomy. First, it facilitates the determination of the appropriate number of groups in which to divide the sample of countries. Second, given that each country has different values for the set of development indicators, cluster analysis allows a synthetic distribution that makes easier comparisons of the development indicators across countries.

Nevertheless, cluster analysis also poses difficulties for the classification of countries. Nielsen (2012) points to two difficulties: first, if the values of the development indicators are evenly distributed across countries, the analysis is not able to distinguish groups, even though there may be important differences between the indicators for each country. However, this limitation does not affect our exercise, as the analysis clearly discerns the ‘association structure’ across developing countries and thus allows us to identify a small number of country groups. Second, Nielsen also argues that clustering techniques allow a large degree of freedom in choosing among alternative measures of distance and cluster algorithms, which in turn complicates the selection of time-invariant variables that can be used in periodic

---

<sup>5</sup>This section draws upon Tezanos (2012) and Tezanos and Quiñones (2012), who previously used cluster analysis for classifying the middle income countries of Latin America and the Caribbean.

updates of the classification. However, this difficulty only applies in the case of restricting the classification over time to the same exact number of groups (regardless of what the cluster analysis suggests).

We argue in this paper that, as the developing world “evolves” over time, cluster analysis can be useful in order to compare the development taxonomies in two different times. Indeed, the analysis suggests that taxonomies ought to be reconsidered every 5-10 years given changes in the developing world. In particular, this analysis allows us to characterize and compare the development clusters built in each period (not necessarily with the same number of groups and, obviously, neither with the same specific countries in each group), and to analyse the dynamics of the development process of a single country in comparative terms (that is, in terms of the average development indicators of the “peer” countries belonging to the same cluster).

In our piece of research, we conduct a hierarchical cluster analysis using the Ward’s method, computing the squared Euclidean distances between each element and standardising the variables in order to correct differences in scale.<sup>6</sup> The analysis includes 99 countries in the period 1995-2000, and 101 in the period 2005-2010 (of the 139 low and middle income countries); hence we are including in the analysis more than 95% of the population of the developing world.<sup>7</sup>

Given the type of data used in this cluster analysis (11 continuous variables), three possible clustering algorithms are the nearest neighbour method, the furthest neighbour method and the Ward’s method (Everitt *et al.*, 2011, Mooi and Sarstedt, 2011). Since there is no objective criterion for selecting the most appropriate method, the selection depends largely on the interpretability of the final results.<sup>8</sup>

---

<sup>6</sup> Regarding the standardisation method, we use the ‘range -1 to 1’ which is deemed to be preferable than other methods ‘in most situations’ (Mooi and Sarstedt, 2011: 247). The analysis was conducted using SPSS software.

<sup>7</sup> The two additional countries included in the later period are Serbia and Montenegro, which were not independent States in 2000. The countries not included in the analysis are either insular states with less than one million inhabitants (Antigua and Barbuda, Dominica, Fiji, Grenada, Kiribati, Maldives, Marshall Islands, Mauritius, Mayotte, Palau, Samoa, Sao Tome and Principe, Seychelles, Solomon Islands, St. Kitts and Nevis, St. Lucia, St. Vincent and the Grenadines, Tonga, Tuvalu and Vanuatu), or countries with limited statistical information (Afghanistan, Bosnia and Herzegovina, Cuba, Eritrea, Kosovo, Lebanon, Libya, Mongolia, Myanmar, North Korea, Somalia, Sudan, Timor-Leste, Uzbekistan, West Bank and Gaza, and Zimbabwe).

<sup>8</sup> See Tezanos and Sumner (2013) for further details on our cluster analysis procedure for building a development taxonomy.

## 4. How has the developing world changed since the late 1990s?

### 4.1. Comparison of the development clusters across time

As noted, the cluster analysis optimally produces five clusters in each of the two analysed periods. The clusters are numbered from one to five in increasing order of GNI *per capita* (Atlas method) solely to make comparisons with the World Bank’s income classification.<sup>9</sup>

There are important differences in the clusters’ composition over time (**Table 2**). Although the first cluster (C1) includes 31 countries in both periods, the second (C2) was composed of 18 countries in 1995-2000 and dropped to nine countries in 2005-2010; the third (C3) included 18 countries in the first period, and increased to 32 in the last one; the fourth (C4) increased over time from 11 to 15 countries; and the fifth (C5) dropped from 21 to 14 countries. Furthermore, the income composition within each cluster (according to the corresponding World Bank’s income classifications in 2000 and 2010) has also changed, as did the total number of countries in each category.<sup>10</sup>

**Table 2. Time variations in the clusters composition**

	1995-2000	2005-2010
<b>C1</b>	<b>31</b>	<b>31</b>
LIC	30	25
LMIC	1	6
UMIC	0	0
<b>C2</b>	<b>18</b>	<b>9</b>
LIC	14	2
LMIC	4	7
UMIC	0	0
<b>C3</b>	<b>18</b>	<b>32</b>
LIC	5	2
LMIC	13	20
UMIC	0	10
<b>C4</b>	<b>11</b>	<b>15</b>
LIC	1	0
LMIC	9	5
UMIC	1	10

<sup>9</sup> Appendix 2 shows the complete set of countries classified by periods, clusters, GNI per capita and income groups.

<sup>10</sup> The overall number of LICs reduced from 51 to 29, and – in return – the number of middle income countries (both LMIC and UMIC) increased (see bottom lines of Table 2).

<b>C5</b>	<b>21</b>	<b>14</b>
LIC	1	0
LMIC	8	1
UMIC	12	13
<b>TOTAL</b>	<b>99</b>	<b>101</b>
LIC	51	29
LMIC	35	39
UMIC	13	33

How can we classify developing countries in the late 1990s and in the current period? A precise interpretation of the time changes of the five clusters involves examining the cluster centroids (i.e. the variables' average values of all countries in a certain cluster and in a certain period, see **Table 3**) so we can compare the average characteristics of each development cluster in the two analysed periods. Overall, the developing world has improved in terms of most of the development indicators (see last section in Table 3, "total"), thus reducing poverty, malnutrition and – to a more limited extent – income inequality; increasing the non-agriculture proportion of GDP, labour productivity and scientific articles production; and improving democracy. However, the overall dependency on primary exports and external finance has increased over time, as well as the CO<sub>2</sub> *per capita* emissions, whereas governance has been virtually static.

Despite this general improvement, the development clusters have changed significantly over time, and differently across clusters. On the one hand, the 1995-2000 development taxonomy depicts the following five groups of developing countries:

- Cluster 1 consists of **very poor countries with largely 'traditional' economies** – in the Dudley Seers (1963 and 1969) sense. These countries had the highest poverty and malnutrition headcounts, the least modernized economies (with the highest contribution of agriculture to GDP and the lowest levels of labour productivity and innovation) and very low governance and democracy indicators. However, the income inequalities were less acute than in C3 and C5 and they had the lowest CO<sub>2</sub> *per capita* emissions. Moreover, many of these economies received relatively high levels of external flows (mainly ODA).
- Cluster 2 consists of **poor countries with democratic regimes but poor governance**. These countries had moderate income inequalities (relative to the average for all developing countries) and the second worst indicators (after C1)

in terms of poverty, malnutrition, non-agricultural GDP, productivity, innovation and CO<sub>2</sub> *per capita* emissions. They also had low proportion of exports in primary products and received moderate external finance. Although they had above-average democracy indicators, their governance indicators were comparatively low.

- Cluster 3 is composed of **countries with democratic regimes but high levels of inequality and dependency on external flows**. These countries ranked third of the clusters in terms of income poverty, malnutrition, non-agricultural GDP, productivity, innovation, and CO<sub>2</sub> *per capita* emissions. However, these countries had the highest levels of income inequality, the lowest proportion of exports in the primary sector, the highest external finance, the second best scores in governance indicators (although still below the developing world average) and the highest democracy indicator.
- Cluster 4 consists of “**emerging economies**” that were **primary product exporting with low inequality but high environmental pollution and severely constrained political freedoms**. These countries had the second lowest poverty and malnutrition headcounts of the clusters, and the second highest indicators of non-agricultural GDP, productivity and innovation capacities. They also had a limited receipt of external finance. However, they had the highest proportion of exports in primary products, the second worst governance indicators of the clusters, the worst democracy indicators and they were the second most polluting countries of the sample.
  - Cluster 5 consists of **highly polluting and unequal emerging economies**. These were the most polluting countries and had the second highest inequality, but the highest non-agricultural GDP, labour productivity and innovation capacities, and the lowest poverty and malnutrition headcounts. They also had comparatively high governance and democracy indicators, and limited dependency on external finance and primary exports.

**Table 3. Development cluster centroids per period**

Development clusters	Period	Poverty	Gini	Malnutrition	Non-agriculture GDP	Primary exports	Productivity	Articles	External finance	WGI	POLITY	CO2pc	For reference: GNIpc
<b>C1</b>	1995-2000	73.39	44.02	23.80	64.63	17.54	3,057.67	2.69	16.55	-0.92	-2.42	0.33	931.61

On the other hand, the development taxonomy in 2005-2010 was as follows:

- *C1* continues to consist of **countries with high poverty rates and largely 'traditional' economies**. Despite the fact that this cluster has the same number of countries in both periods, it is important to note that this cluster has experienced the highest number of movements across clusters. Nine countries moved from *C1* to *C2* between the two periods (Angola, Cameroon, Chad, Republic of Congo, Mauritania, Swaziland, Tajikistan, Vietnam and Yemen), thus moving into a cluster with better average values. Three *C1* countries moved to *C3* (Bhutan, Kenya and Kyrgyz Republic).
- *C2* also changed, and dramatically, over time. Indeed, all countries in *C2* are different between the two analysed periods. In the second period, *C2* groups **countries with high poverty and malnutrition rates that are primary product exporting and have limited political freedoms**. Therefore, although *C2* includes countries with high poverty and traditional economies in both periods (i.e. these countries rank second, after *C1*, in terms of poverty, malnutrition, non-agricultural GDP, productivity and innovation), in the 1990s it was a group of countries with democratic regimes but poor governance (e.g. India, Philippines, Senegal and Madagascar), and currently become a group of – different – countries that have severely constrained political freedoms and high dependency on natural resource exports (e.g. Angola, Chad, Republic of Congo and Vietnam).
- *C3* remains composed of **countries with democratic regimes and high levels of inequality and dependency on external flows**. However, *C3* almost doubled its size over time (from 18 to 32 countries). In fact, the 18 countries included in *C3* in the 1990s remain in this cluster in the latter period, plus other 14 new countries. Cape Verde, El Salvador, Honduras, Lesotho and Nicaragua are, for example, members of this cluster.
- *C4* also remained similar over time –“**emerging economies**” **who are primary product exporting with low inequality but high environmental pollution and limited political freedoms** –, although four new primary-exporting emerging economies joined this group in 2005-2010 (Belarus, Iran, Jordan and Venezuela).

- Finally, *C5* – **unequal and highly polluting “emerging economies” with low dependence on external finance** – did not change its main development features overtime, although seven countries left this cluster in the last period (precisely the four new members of *C4* previously noted above, plus Macedonia, South Africa, Panama and Thailand, who joined *C3*).

In short, the development characteristics of four of the five clusters remain similar over time, but *C2* changed dramatically. A third (38) of all developing countries in the sample of 101 changed cluster membership between these two periods, and the remainder – the majority – of the developing countries remain in the same cluster (but, it should be borne in mind that groups, at the same time, have evolved over time).

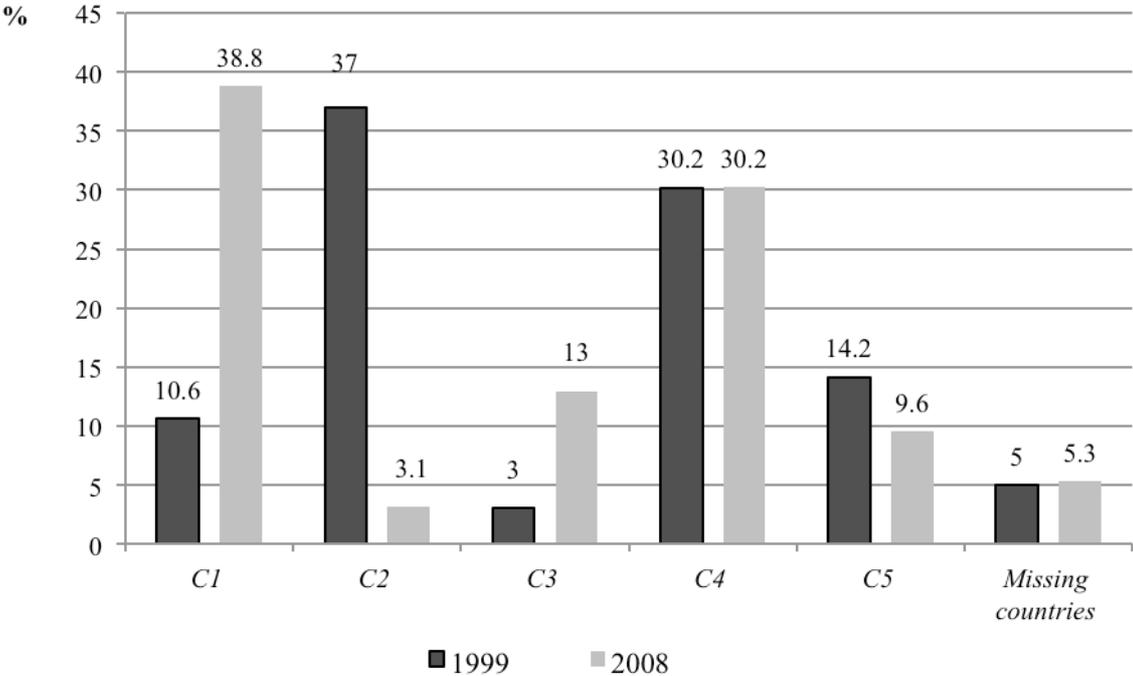

Moreover, this ‘dynamic’ results mean that – as noted in Tezanos and Sumner (2013) – there is no simple ‘linear’ representation of development levels (from low to high development countries), as is implied with the income *per capita* – ranking – classification. Instead, each cluster of countries has its own and specific development issues and there is no group of countries with the best (or worst) indicators in all the development dimensions. Whereas the income classification depicts a linear development process where all countries are assessed as if they were following a similar ‘development path’ of income growth – as described, for example, by Rostow’s ‘stages of growth’ –, regardless of other development dimensions, our taxonomy may offer a somewhat more nuanced understanding of the diversity of challenges of developing countries, and their evolution over time.

#### **4.2. Distribution of global population and poverty across time**

The clusters classification has important implications in terms of the evolution of the developing world’s population distribution (**Figure 1**): in the late 90s, about 11 per cent of the developing countries’ population was concentrated in *C1*, 37 per cent was concentrated in *C2* (which included some of the most populated countries of the world, like India, Pakistan and Bangladesh); 30 per cent in *C4* (due to China), and 17 per cent was distributed across *C3* and *C5*. By contrast, the population distribution changed sharply in the 2000s, due to the movement of India into *C2* (this cluster now

represents almost 39 per cent of developing countries population), and the increase in C3 (due to the incorporation of 14 new countries in this group).

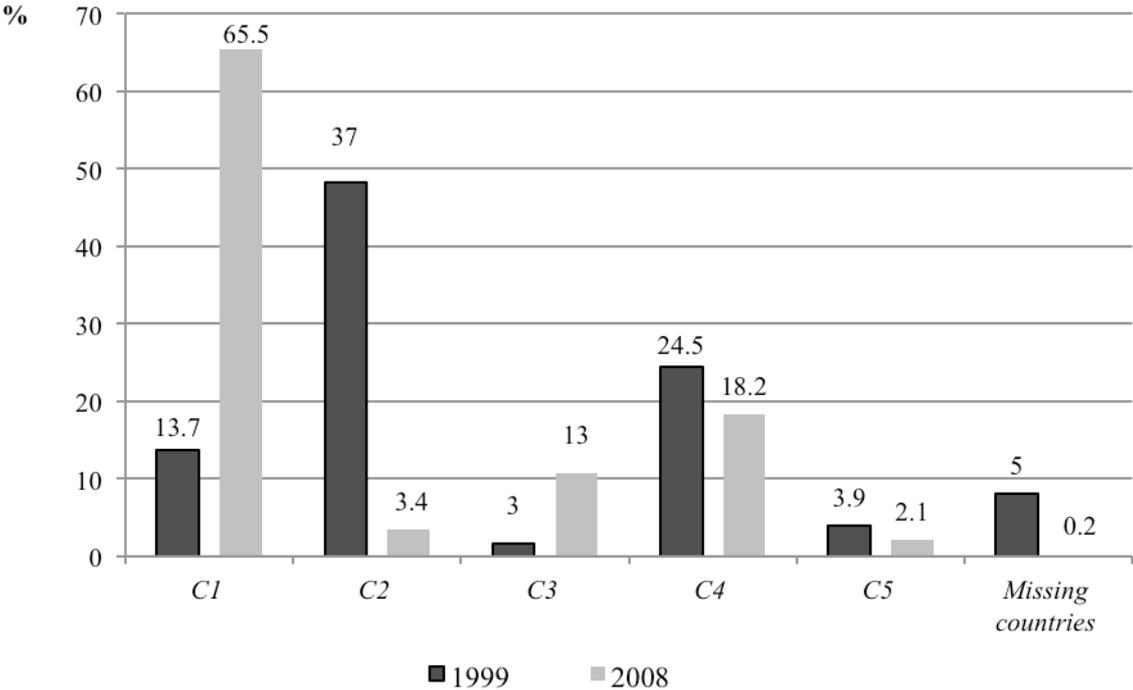

**Figure 1. Population distribution across development clusters**

If we consider the distribution of \$2 poverty in our development taxonomy (**Figure 2**), we find that in the late 90s, the two poorest development clusters (C1 and C2) concentrated almost two thirds of the world's poor (specially C1, due to India, Pakistan and Bangladesh), another 24.5 per cent lived in C4 (due to China), and 5.5 per cent was scattered across C3 and C5. One decade later, almost two thirds of the world's poor live in C1 (due to the incorporation of India, that accounts for a third of global poverty), 18 per cent live in C4 (the group with overall good development indicators but bad governance), 11 per cent live in C3, and 5.5 per cent live in C2 and C5. In sum, the aggregate contribution of C1 and C2 to global poverty in both periods is larger than their aggregate contribution to population. Therefore, the two clusters with the greatest development challenges (C1 and C2) concentrate the majority of the world poor, which sharply contrast with the income classification, were the 'poorest' group (LIC) concentrates one fifth of the global \$2 poor. In short, our taxonomy reveals a close relation between income poverty and other development problems (such as low levels of productivity and innovation, weak governance, and

high dependency on agriculture). It should also be noted that *poverty* is the variable with the greatest discriminating power in the cluster analysis – as it was previously tested with the ANOVA analysis – which in turns implies that countries in *C1* and *C2* share the distinct feature of having high poverty headcounts (and “moderate” income inequalities, in comparison with the other clusters, due to the fact that the majority of the population live under the \$2 poverty line).

**Figure 2. Poverty distribution across development clusters**

## 5. Conclusions

This paper has sought to address the question of just how much the developing world has really changed since the late 1990s. The paper outlines a multidimensional taxonomy of developing countries and considers how groups have evolved over time.

The main findings are as follows: First, the developing world can be classified into five multidimensional development clusters and this number of clusters remains the same between the periods 1995-2000 and 2005-2010. However, not surprisingly, the nature of the clusters has changed over time. Four clusters remain *largely* the same: *C1* is composed of “countries with high poverty rates and largely traditional economies”; *C3* are “countries with democratic regimes but high levels of inequality and dependency on external flows”; *C4* are “emerging economies who are primary-exporting with low inequality but high environmental pollution and limited political freedoms”; and *C5* are “unequal and highly polluting emerging economies with low dependence on external finance”.

In terms of the specific countries in each cluster, it is in *C1* – very poor countries with largely ‘traditional’ economies – where there has been the highest number of movement of countries in and out (in particular, nine countries moved out of this cluster and towards *C2*).

Indeed, *C2* has changed dramatically over time in composition of countries and development characteristics. Although this cluster includes countries with high poverty and traditional economies in both periods, it was a group of “countries with democratic regimes but poor governance in the first period” (e.g. India, Philippines, Senegal and Madagascar), and become a group of “countries that have severely constrained political freedoms and high dependency on natural resource exports” (such as Angola, Chad, Republic of Congo and Vietnam).

*C3* has changed too in terms of the number of countries in the cluster – it has doubled in size with all of the countries included in *C3* in 1995-2000 remaining in this cluster in 2005-2010 but joined by 14 new countries such as El Salvador, Honduras, Lesotho and Nicaragua. Interestingly *C4* emerging economies remained largely the same as did *C5*.

If we return to the question of why classify developing countries that was posed at the outset, we would argue that the clustering approach has some particular strengths. Firstly, for *analytical reasons*: a cluster approach has the advantages of

not only tracking movements of countries over time by cluster but by identifying the changing development needs/problems of each cluster.

Secondly, for *operational reasons*: such a cluster approach has the advantages of grouping countries by needs that development co-operation might address. Further, a cluster approach can facilitate the countries of the same group collectively identifying specific development strategies for the group and thus the taxonomy may be useful for guiding South-South co-operation policies.

We can further note that cluster analysis itself has four features which make it particularly appropriate for the purpose of producing useful development taxonomy within the area of Development Studies: i) The cluster analysis has the advantage of providing country classifications that are reasonably 'objective' (in the sense that the analysis of the same set of countries by the same numerical methods produces similar classification) and 'stable' (in that the classification remains similar when new countries, or new characteristics describing them, are added). ii) Cluster analysis deals with two intrinsic problems of the design of a development taxonomy, the determination of the appropriate number of groups in which to divide countries and the construction of a synthetic distribution that makes easier comparison of the development indicators across countries. iii) Cluster analysis can be used to replicate the taxonomy in different periods in order to analyse the dynamics of the development process of each country in comparative terms. And finally, iv) the taxonomy does not offer a simple 'linear' representation of development levels (from low to high development countries), but something that better represents the reality of non-linear development process.

However, perhaps the two greatest challenges to the cluster approach are that, firstly, the cluster analysis is a more complex taxonomy than other approaches (partly because it captures much more). It is not without reason that income-based classifications thrive – it is mainly because of their simplicity... even if that is misleading. And secondly, the cluster analysis is open to accusations – like existing classifications – relating to the "approximate" nature of any proxy. Whilst any choice of indicator is somewhat arbitrary, what we have sought to do is to base the choice on a consideration of the theoretical debate in identifying 'frames' of development and considering what indicators are available and largely used by other researches.
